SECTION 13

Storage

An on-farm storage system designed for good hygiene that includes aeration and sealable silos for fumigation is essential for growers who wish to maximise their returns from wheat (Figure 1). Without sealable silos, growers could be contributing to Australia's problem of insect resistance to phosphine, the most common fumigant used in the Australian grain industry. Without aeration, growers risk excluding themselves from markets that will not accept chemically treated grain.

In conjunction with sound management practices, which include checking grain temperatures and regular monitoring for insect infestations, an on-farm storage system that is well designed and maintained and properly operated provides the best insurance a grower can have on the quality of grain to be out-turned.

Figure 1: Storage with aeration is important for protecting Australia's markets. (Photo: QDAFF)

Grain Trade Australia (GTA) stipulates standards for heat-damaged, bin-burnt, storage-mould-affected or rotten wheat, all of which can result in the discounting or rejection of grain. GTA has nil tolerance to live, stored-grain insects for all grades of wheat from premium milling grades to feed.¹ Effective management of stored grain can eliminate all of these risks to wheat quality.

In grain storages in target grain temperatures of stored wheat should be 20–23°C during summer and <15°C in winter.²

13.1 How to store wheat on-farm

According to the Kondinin Group National Agricultural Survey 2011, silos account for 79% of Australia's on-farm grain storage, compared with 12% for bunkers and pits and 9% for grain bags.

Aerated silos that can be sealed during fumigation are widely acknowledged as the most effective way to store wheat on-farm (Table 1). There is now an Australian standard (AS2628) for sealable silos that manufacturers in Australia can choose to use as a construction standard to ensure reliable fumigation results.

Watch this GRDC Ground Cover TV clip to find out more.

Table 1: Advantages and disadvantages of grain storage options

Storage type	Advantages	Disadvantages
Gas-tight sealable silo	<ul style="list-style-type: none"> Gas-tight sealable status allows phosphine and controlled atmosphere options to control insects Easily aerated with fans Fabricated on-site or off-site and transported Capacity from 15 to 3000 t Service life up to 25 years or more Simple in-loading and out-loading Easily administered hygiene (cone base particularly) Can be used multiple times in-season 	<ul style="list-style-type: none"> Requires foundation to be constructed Relatively high initial investment required Seals must be regularly maintained Access requires safety equipment and infrastructure Requires an annual test to check gas-tight sealing
Non-sealed silo	<ul style="list-style-type: none"> Easily aerated with fans 7–10% cheaper than sealed silos Capacity from 15 to 3000 t Service life up to 25 years or more Can be used multiple times in-season 	<ul style="list-style-type: none"> Requires foundation to be constructed Silo cannot be used for fumigation—see phosphine label Insect-control options limited to protectants in eastern states and Dryacide® in Western Australia Access requires safety equipment and infrastructure

Storage type	Advantages	Disadvantages
Grain storage bags	<ul style="list-style-type: none"> • Low initial cost • Can be laid on a prepared pad in the paddock • Provide harvest logistics support • Can provide segregation options • Are all ground-operated • Can accommodate high-yielding seasons 	<ul style="list-style-type: none"> • Requires purchase or lease of loader and unloader • Increased risk of damage beyond short-term storage (typically 3 months) • Limited insect-control options, fumigation only possible under specific protocols • Requires regular inspection and maintenance, which needs to be budgeted for • Aeration of grain in bags currently limited to research trials only • Must be fenced off • Prone to attack by mice, birds, foxes, etc. • Limited wet-weather access if stored in paddock • Need to dispose of bag after use • Single-use only
Grain storage sheds	<ul style="list-style-type: none"> • Can be used for dual purposes • Service life 30 years or more • Low cost per stored tonne 	<ul style="list-style-type: none"> • Aeration systems require specific design • Risk of contamination from dual-purpose use • Difficult to seal for fumigation • Vermin control is difficult • Limited insect-control options without sealing • Difficult to unload

Growers should pressure-test sealable silos once a year to check for damaged seals on openings. Storages must be able to be sealed properly to ensure that high concentrations of phosphine gas are held long enough to give an effective fumigation.

At an industry level, it is in growers' best interests to fumigate only in gas-tight sealable storages to help stem the rise of insect resistance to phosphine. This resistance has come about because of the prevalence of storages that are poorly sealed or unsealed during fumigation.³

The Kondinin Group National Agricultural Survey 2009 revealed that 85% of respondents had used phosphine at least once during the previous 5 years, and of those users, 37% used phosphine every year for the past 5 years. A GRDC survey during 2010 revealed that only 36% of growers using phosphine applied it correctly—in a gas-tight, sealable silo.

Research shows that fumigating in a storage that is not gas-tight does not achieve a sufficient concentration of fumigant for long enough to kill pests at all stages of the life cycle. For effective phosphine fumigation, a minimum gas concentration of 300 parts per million (ppm) for 7 days or 200 ppm for 10 days is required. (Figure 2). Fumigation trials in silos with small leaks demonstrated that phosphine levels are as low as 3 ppm close to the leaks. (Figure 3). The rest of the silo also suffers from reduced gas levels.⁴

Aeration of stored wheat is the key non-chemical tool used to minimise the risk of insect infestations and spoiling through heat and/or moisture damage.

Aeration controllers that automatically monitor air temperature and humidity are designed to turn fans on and off at the optimum times. The controller reduces the risk of having fans running on storages at times that potentially cause grain damage. Most aeration controllers have hour meters fitted, so run-times can be checked to ensure they are within range of the expected total average hours per month, for example, 100 h/month.

It is important to separate aeration systems commonly used for 'aeration cooling' and aeration systems designed specifically to achieve reliable 'aeration drying'. Serious grain damage has occurred when fan performance has not met the required airflow rates as measured in litres per second per tonne (L/s.t).

If aeration drying of grain is attempted with elevated moisture levels while using an inadequate airflow rate and/or a poor system design, sections of the storage can develop very high moisture and grain temperatures. With low airflow rates, moisture-drying fronts move too slowly to prevent grain spoilage. Losses of grain quality from moulds and heat occur rapidly. This type of damage often makes the grain difficult to sell and may cause physical damage to the silo itself.⁵

⁵ P Burrill, A Ridley, C Saunders, A Andrews, A Kotzur (2012) Performance testing aeration systems. Grain Storage Fact Sheet, GRDC, August 2012, <http://www.grdc.com.au/Resources/Factsheets/2012/08/Grain-Storage-Performance-testing-aeration-systems>

Researchers in Australia have developed a device that measures working airflow rates of fans fitted to grain storage. Called the 'A-Flow', it has been validated under controlled conditions, using an Australian Standard fan-performance test rig, to be within 2.6% of the true fan output. The device was used on a typical grain storage that was in the process of aerating recently harvested grain. A fan advertised to provide 1000 L/s (equivalent to 6.7 L/s.t on a full silo of capacity 150 t) was tested and shown to be producing only 1.8 L/s.t. Because of this test, the farmer recognised a need to make changes to his current aeration system design.

Several changes may be required if airflow rates are not suitable for efficient aeration cooling or drying. A new fan that is better suited to the task could be installed, or the amount of grain in the silo reduced to increase flow rate per tonne of grain.

Detailed information about selecting, siting and fitting-out silos, grain storage bags, sheds and bunkers is contained in the GRDC Grains Industry Guide: [Grain storage facilities—planning for efficiency and quality](#).

A GRDC Fact Sheet explaining how to build and use an A-Flow is available at: [Performance testing aeration systems](#).

[GRDC: Grain storage facilities—planning for efficiency and quality](#)

13.2 Hygiene

Effective grain hygiene and aeration cooling can overcome 75% of pest problems in stored grain (Figure 4). All grain residues should be cleaned out when silos and grain-handling equipment are not in use to help minimise the establishment and build-up of pest populations.

In a single year, a bag of infested grain can produce more than one million insects, which can walk and fly to other grain storages where they will start new infestations. Meticulous grain hygiene involves removing any grain residues that can harbour pests and allow them to breed. Grain pests live in protected, sheltered areas in grain handling equipment and storage and breed best in warm conditions. Insects will also breed in outside dumps of unwanted grain. Try to bury grain or spread unwanted grain out to a shallow depth of <20 mm so that insects are exposed to the daily temperature extremes and to other insect predators.

Figure 4: Poor grain hygiene undermines effective stored grain insect control. (Photo: QDAFF)

A trial in Queensland revealed >1000 lesser grain borers (*Rhyzopertha dominica*) (Figure 5) in the first 40 L of grain through a harvester at the start of harvest. This harvester was considered reasonably clean at the end of the previous season.⁶

Further studies in Queensland revealed that insects are least mobile during the colder winter months of the year. Cleaning around silos during winter can reduce insect numbers before they become mobile.

Figure 5: Lesser grain borer, *Rhyzopertha dominica*. (Photo: QDAFF)

Successful grain hygiene involves cleaning all areas where grain residues become trapped in storages and equipment. Grain pests can survive in a tiny amount of grain, which can go on to infest freshly harvested, clean grain. Harvesters and grain-handling equipment should be cleaned out thoroughly with compressed air after use.

After grain storages and handling equipment are cleaned, they should be treated with a structural treatment. Diatomaceous earth (DE) is an amorphous silica also commonly known as the commercial product Dryacide® and is widely used for this purpose. It acts by absorbing the insect's cuticle or protective waxy exterior, causing death by desiccation. If applied correctly with good coverage in a dry environment, DE can provide up to 12 months of protection by killing most species of grain insects and with no known risk of resistance. It can be applied as a dry dust or slurry spray.

Although many cereal grain buyers accept approved, chemical insecticide structural treatments to storages, growers should avoid using them, or wash the storage out, before storing oilseeds and pulses. Several export and domestic markets now require 'pesticide residue free' (PRF) grain; therefore, growers are advised to check with potential grain buyers before using grain protectants or structural treatments.

To find out more about what to use and when, and how to clean equipment and storages to minimise the chance of insect infestation, download the GRDC Grain Storage Fact Sheet [Hygiene and structural treatment for grain storages](http://www.grdc.com.au/Resources/Factsheets/2013/06/Grain-Storage-Fact-Sheet-Grain-Storage-Pest-Control-Guide).

13.3 Grain protectants and fumigants

Grain Trade Australia is aware of cases where chemicals that are not approved for grain or a particular grain type have been used to treat stored grain. When such cases are detected, an entire shipload can be rejected, often with serious long-term consequences for important Australian grain markets.

Market requirement for PRF grain does not rule out the use of some fumigants, including phosphine (Figure 6). However, PRF grain should not have any chemical residues from treatments that are applied directly to the grain as grain protectants. Before using a grain protectant or fumigant, growers need to check with prospective buyers, because the use of some chemicals may exclude grain from certain markets.

Although phosphine has resistance issues, it is widely accepted as having no residue problems. The grain industry has adopted a voluntary strategy to manage the build-up of phosphine resistance in pests. Its core recommendations are to limit conventional phosphine fumigations on undisturbed grain to three per year, and to employ a break strategy. The break is provided by moving the grain to eliminate pockets where the fumigant may fail to penetrate, and by retreating it with an alternative disinfestant or protectant.⁷

Figure 6: Phosphine is widely accepted as having no residue issues. (Photo: QDAFF)

Research has identified the genes responsible for insect resistance to phosphine. A genetic analysis of insect samples collected from south-eastern Queensland between 2006 and 2011 has allowed researchers to confirm the increasing incidence of phosphine resistance in the region. Whereas few resistance markers were found in insects collected in 2006, by 2011, most collections had insects that carried the resistance gene. Further testing with DNA markers that can detect phosphine resistance is expected to identify problem insects before resistance becomes entrenched, thereby

⁷ P Collins (2009) Strategy to manage resistance to phosphine in the Australian grain industry. Cooperative Research Centre for National Plant Biosecurity Technical Report, http://www.graintrade.org.au/sites/default/files/file/Phosphine_Strategy.pdf

helping to prolong phosphine's effective life, as well as increasing the usefulness of the break strategy.⁸

Chemical options for treatment of stored grain, and efficacy against various stored grain insects, are presented in Table 2.

Table 2: Stored grain chemical treatments: resistance and efficacy guide for stored grain insects (northern and southern regions) in cereal grains

Treatments	WHP (days)	Lesser grain borer (<i>Rhyzopertha dominica</i>)	Rust-red flour beetle (<i>Tribolium castaneum</i>)	Rice weevil (<i>Sitophilus oryzae</i>)	Saw-toothed grain beetle (<i>Oryzaephilus surinamensis</i>)	Flat grain beetle (<i>Cryptolestes ferrugineus</i>)	Psocids (booklice) (Order Psocoptera)	Structural treatments
Grain disinfectants - used on infested grain to control full life cycle (adults, eggs, larvae, pupae).								
Phosphine (eg Fumitoxin [®]) ^{A,C} when used in gas-tight, sealable stores	2							
Sulfuryl fluoride (eg ProFume [®]) ^J	1							
Dichlorvos (eg Dichlorvos 1140 [®]) ^K	7-28							I
Grain protectants - applied post harvest. Poor adult control if applied to infested grain.								
Pirimiphos-methyl (eg Actellic 900 [®])	nil ₂							
Fenitrothion (eg Fenitrothion 1000 [®]) ^D	1-90							
Chlorpyrifos-methyl (eg reldan Grain Protector [®]) ^E	nil _B							
Methoprene (Grain Star 50 [®])	nil ^F		G		G			
'Combined products' (eg Reldan Plus IGR Grain Protector)	nil _B							
Deltamethrin (eg K-Obiol [®]) ^J	nil _B							
Diatomaceous earth, amorphous silica - effective internal structural treatment for storages and equipment. Specific use grain treatments.								
Diatomaceous earth, amorphous silica (eg Dryacide [®]) ^H	nil _B							

WHP Withholding Period; DE, diatomaceous earth.

Not registered for this pest

High-level resistance in flat grain beetle has been identified, send insects for testing if fumigation failures occur

Resistant species likely to survive this structural treatment for storage and equipment

Resistance widespread (unlikely to be effective)

Effective control

^A unlikely to be effective in unsealed sites, causing resistance, see label for definitions

^B When used as directed on label

^C Total of (exposure + ventilation + withholding) = 10 to 27 days

^D Nufarm label only

^E Stored grains except malting barley and rice/ stored lupins registration for Victoria only/ not on stored maize destined for export

^F When applied as directed, do not move treated grain for 24 hours

^G Periods of 6-9 months storage including mixture in adjuvant, eg Fenitrothion at label rate

^H Do not use on stored maize destined for export, or on grain delivered to bulk-handling authorities

^I Dichlorvos 500g/L registration only

^J Restricted to licensed fumigators or approved users

^K Restricted to use under permit 14075 only. Unlikely to be practical for use on farm

⁸ C Norwood (2013) Genetic clue to thwart phosphine resistance. GRDC Ground Cover, Issue 102, Jan.-Feb. 2013, <http://www.grdc.com.au/Media-Centre/Ground-Cover/Ground-Cover-Issue-102/Genetic-clue-to-thwart-phosphine-resistance>

According to research at Queensland's Department of Agriculture, Fisheries and Forestry (DAFF), sulfuryl fluoride (SF) has excellent potential as an alternative fumigant to control phosphine-resistant grain-storage pests (Table 2). It is currently registered in Australia as a grain disinfectant. Supplied under the trade name ProFume®, SF can be used only by a licensed fumigator.

Field trials have shown that SF can control strongly phosphine-resistant populations of the rusty grain beetle. Monthly sampling of fumigated grain has revealed no live insects for three consecutive months in large-scale bunker (pad) storages after the fumigation.

Annual resistance-monitoring data were analysed to assess the impact of using SF as an alternative fumigant to phosphine. After the introduction of SF in central storages across the northern and southern grain regions in 2010, there was a 50% reduction in the incidence of strongly phosphine-resistant populations of rusty grain beetle at the end of the first year, and the downward trend continues. Complimentary laboratory experiments have shown that phosphine resistance does not show cross-resistance to SF, which is an additional advantage of using SF.⁹

Effective phosphine fumigation can be achieved by placing the chemical at the rate directed on the label onto a tray and hanging it in the top of a pressure-tested, sealable silo. A ground-level application system is also efficient and can be combined with a silo recirculation system on larger silos to improve the speed of gas distribution. After fumigation, grain should be ventilated for a minimum of 1 day with aeration fans running, or 5 days if no fans are fitted. A minimum withholding period of 2 days is required after ventilation before grain can be used for human consumption or stockfeed. Total time required for fumigating ranges from 7 to 20 days depending on grain temperature and the storage structure.

To find out more, visit: [Fumigating with phosphine, other fumigants and controlled atmospheres: Do it right—do it once: A Grains Industry Guide](#).

Two new grain protectants are now available:

- K-Obiol® (active ingredients deltamethrin 50 g/L, piperonyl butoxide 400 g/L). Features acceptable efficacy against the common storage pest lesser grain borer, which has developed widespread resistance to current insecticides. Insect resistance surveys have consistently detected low levels of deltamethrin-resistant insect strains in the industry. This is a warning that resistant populations could increase quickly with widespread excessive use of one product. A 'product stewardship' program has been developed to ensure correct use of the product.¹⁰
- Conserve™ On-Farm. Has three active ingredients (chlorpyrifos-methyl 550 g/L, S-methoprene 30 g/L, spinosad 120 g/L) to control most major insect pests of stored grain, including the resistant lesser grain borer. Maximum residue limits have been established with key trading partners and there are no issues with meat residue bioaccumulation.

A grain disinfectant combined with carbon dioxide gas currently has some limitations:

- VAPORMATE® (active ingredient ethyl formate 166.7 g/kg). Approved for use in stored cereals and oilseeds. It is registered to control all life stages of the major storage pest insects: lesser grain borer, rust-red flour beetle, saw-toothed beetle, flat grain beetles, storage moths and psocids (booklice). However, it does not fully control all stages of rice weevil. Must only be used by a licensed fumigator.

⁹ M Nayak (2012) Sulfuryl fluoride—a solution to phosphine resistance? GRDC Grains Research Update Northern Region, Spring 2012, Issue 66, <https://www.grdc.com.au/-/media/DAF5F438D9644D90B9A4FA9716B2014E.pdf>

¹⁰ P Burrill (2013) Grain Storage Future pest control options and storage systems 2013–2014. GRDC Update, 18 July 2013, <https://www.grdc.com.au/Research-and-Development/GRDC-Update-Papers/2013/07/Grain-Storage-Future-pest-control-options-and-storage-systems-2013-2014>

Controlled atmosphere or non-chemical treatment options include:

- Carbon dioxide (CO₂). Displaces the oxygen inside a gas-tight silo with a high concentration of CO₂ combined with a low-oxygen atmosphere lethal to grain pests. To achieve complete kill of all grain pests at all life stages, CO₂ must be maintained at a minimum concentration of 35% for 15 days.
- Nitrogen (N₂). Provides insect control and quality preservation without chemicals. It is safe to use and environmentally acceptable. The main operating cost is electricity used by the equipment to produce nitrogen gas. The process uses pressure swing adsorption technology to produce N₂, thereby modifying the atmosphere within the grain storage to create a very high concentration of N₂, and starving insect pests of oxygen.¹¹ There are no residues, so grains can be traded at any time

Silo bags as well as silos can be fumigated (Figure 7). Research conducted by Andrew Ridley and Philip Burrill from DAFF Qld, and Queensland farmer Chris Cook, found that sufficient concentrations of phosphine can be maintained for the required time to fumigate grain successfully in a silo bag. Fumigation trials on a typical, 75-m-long bag containing ~230 t of grain successfully controlled all life stages of the lesser grain borer.

Figure 7: Silo bags can also be fumigated. (Photo: QDAFF)

When using phosphine in silos or silo bags, phosphine tablets are not to be mixed directly with grain because of tablet residue issues. Trays in silo bags are not practical; therefore, tablets are placed in perforated conduit to contain tablets and spent dust. The 1-m tubes are speared horizontally into the silo bag and removed at the end of the fumigation. Trial results suggest that the spears should be no more than 7 m apart and fumigation should occur over 12–14 days (Figure 8). In trials where spears were spaced 12 m apart, the phosphine gas took too long to diffuse throughout the whole bag.¹²

13.4 Aeration during storage

Aeration has a vital role in both maintaining grain quality attributes and reducing insect pest problems in storage. Most grain in storage is best held under aeration cooling management with the silo having appropriate roof venting. Generally, silos should be sealed up only during a fumigation operation, which typically last for 1 or 2 weeks.

Aeration typically reduces stored grain temperatures by $>10^{\circ}\text{C}$ during summer (Figure 9), which significantly reduces the threat of a serious infestation of insects.¹³

Figure 9: Comparison of wheat grain temperatures in aerated and non-aerated silos.

As soon as grain is harvested and put in storage, run the aeration system non-stop for the first 5 days to reduce grain temperatures and produce uniform moisture conditions in the grain bulk. Without aeration, grain holds its heat, being an effective insulator, and will maintain its warm harvest temperature for a long time (Figure 9). Wheat at typical harvest temperatures of $28\text{--}35^{\circ}\text{C}$ and moisture content $>13\text{--}14\%$ provides ideal conditions for mould and insect growth (Table 3).¹⁴

¹³ P Burrill (2013) Grain Storage Future pest control options and storage systems 2013–2014. GRDC Update Papers, 18 July 2013, <https://www.grdc.com.au/Research-and-Development/GRDC-Update-Papers/2013/07/Grain-Storage-Future-pest-control-options-and-storage-systems-2013-2014>

¹⁴ P Burrill, P Botta, C Newman, B White, C Warrick (2013) Dealing with high-moisture grain. Grain Storage Fact Sheet, GRDC, June 2013, <https://www.grdc.com.au/Resources/Factsheets/2013/06/Grain-Storage-Dealing-with-highmoisture-grain>

Table 3: Effect of grain temperature on insects and mould (source: Kondinin Group)

Grain temperature (°C)	Insect and mould development	Grain moisture content (%)
40-55	Seed damage occurs, reducing viability	
30-40	Mould and insects are prolific	>18
25-30	Mould and insects active	13-18
20-25	Mould development is limited	10-13
18-20	Young insects stop developing	9
<15	Most insects stop reproducing, mould stops developing	<8

Although adult insects can still survive at low temperatures, most stages of the life cycle of storage pests are very slow or development is stopped at temperatures below 18–20°C. One of the more cold-tolerant pests, the common rice weevil, does not increase its population at grain temperatures <15°C. The life cycles of insect pests (egg, larvae, pupae and adult) are lengthened from the typical 4 weeks at warm temperatures (30–35°C) to 12–17 weeks at cooler temperatures (20–23°C).

Research also shows that wheat at 12% moisture content stored for 6 months at 30–35°C (unaerated grain temperature) will have reduced germination percentage and seedling vigour.

A national upper limit for moisture of 12.5% applies to wheat at receipt, but deliveries are usually in the range 10.5–11%.¹⁵ Special measures must be taken to minimise the risk of insect infestations or heat damage if the wheat is harvested in damp conditions.

Research by the NSW Department of Primary Industries has shown that grain temperature should be kept below 15°C to protect seed quality and stop all major insect infestations, and aeration slows the rate of deterioration of seed if the moisture content is kept at 12.5–14%.¹⁶

A trial by DAFF Qld revealed that high-moisture grain generates heat when placed into a confined storage such as a silo. Wheat with 16.5% moisture content at a temperature of 28°C was put into a silo with no aeration. Within hours, the grain temperature reached 39°C and within 2 days reached 46°C, providing ideal conditions for mould growth and grain damage (Figure 10).¹⁷

Figure 10: Effects of temperature and moisture on stored grain. (Source: CSIRO Ecosystems Sciences as published in <http://www.grdc.com.au/~media/36D51B725EF44EC892BCD3C0A9F4602C.pdf>)

If the use of a grain dryer is not an option, grain that is over the standard safe storage moisture content of 12% and up to the moderate moisture level of 15% can be managed by aerating until drying equipment is available. Blending with low-moisture grain and aerating is another commonly used strategy (Figure 11).

Figure 11: Correct blending with low-moisture grain. (Source: Kondinin Group)

Aeration drying forces large volumes of air through the grain in storage and slowly removes moisture. Supplementary heating can be added when ambient conditions typically have high humidity. Aeration drying can be done in a purpose-built drying silo or a partly filled silo with high-capacity aeration fans.

Dedicated driers can be used to dry wheat in batches or with continuous-flow, before it is put into silos, but excessive heat applied post-harvest can reduce the quality of milling wheat.

A wet harvest or damp conditions can make drying prior to storage a necessity. These rules will help you to decide whether it is safe to store your wheat without drying:

More information

GRDC Fact Sheet:
[Dealing with high-moisture grain](#)

- Wheat that does not exceed the maximum moisture level of 12.5% can be aeration-cooled without drying to slow insect development and maintain quality during storage.
- Grain of <15% moisture can be safely held under continuous aeration for a number of weeks until a hot-air drier or an aeration-drying process can take place to reduce the moisture for safe, longer term storage. Blending with dry grain and aerating may also be feasible.
- Grain of >15% moisture should be dried to a safe storage moisture immediately, and then held under normal aeration cooling for maintenance.

13.5 Monitoring wheat

Growers are advised to monitor all grain in storage at least monthly. During warm periods in summer, if grain moisture content is near the upper end of the safe storage moisture content, monitoring every 2 weeks is advisable. Insect pests present in the on-farm storage environment must be identified so that growers can exploit the best use of chemical and/or non-chemical control measures.

Wheat for domestic or export use must not contain live storage pests, and feed grades can lose nutritional value and palatability through infestations. Keeping storage pests out of planting seed grain is also important because they can reduce the germination and vigour of seed, with serious consequences for the next wheat crop.

When monitoring stored grain through sieving, trapping and quality inspections, growers should keep records of findings. If possible, grain temperature should also be checked regularly. Any grain treatments applied need to be recorded (Figure 12).¹⁸

The lesser grain borer and rust-red flour beetle are two of the most common insect pests found in stored cereals. Other common species include weevils, the saw-toothed grain beetle, flat grain beetles and rusty grain beetle, psocids (booklice), Indian meal

Grain Storage Fact Sheet, GRDC, September 2010, <https://www.grdc.com.au/-/media/ReFocus-media-library/Document/GRDC-Documents/Publications-Media-and-Communications/Factsheets/Grain-storage-FS-Aeration-cooling-for-pest-control.pdf>

moth (*Plodia interpunctella*) and angoumois grain moth (*Sitotroga cerealella*). Another dozen or so beetles, and mites, are sometimes present as pests in stored cereal grain.

Photographs and descriptions of these pests can be found in the GRDC Grain Storage Fact Sheet [Northern and southern regions stored grain pests—identification](#), or the GRDC [Stored grain pests identification—the Back Pocket Guide](#).

The Fact Sheet also outlines how to monitor stored grain for infestations. Here are some basic points to follow when monitoring for insect pests in your grain:

- Sample and sieve grain from the top and bottom of grain storages every month (4 weeks) for early pest detection. Pitfall traps installed in the top of the grain store will also aid early detection of storage pests.
- Holding an insect sieve in the sunlight will encourage insect movement, making pests easier to see. Sieve samples onto a white tray, again, to make small insects easier to see. Sieves should have 2-mm mesh and need to hold at least 1 L of grain.
- To help identify live grain pests, place them into a clean glass container. Briefly warm the jar in the sun to encourage insect activity. Weevils and saw-toothed grain beetles can walk up the walls of the glass easily, but flour beetles and lesser grain borer cannot. Look closely at the insects walking up the glass—weevils have a curved snout at the front and saw-toothed grain beetles do not.¹⁹

Research in Queensland has shown that the grain industry may need to consider an area-wide approach to pest and resistance management. The research indicates flight dispersal by the lesser grain borer and the rust-red flour beetle, both of which are major insect pests of stored grain. Beetle traps were set along a 30-km transect in the Emerald district and showed that the lesser grain borer flies all year round in Central Queensland, whereas the flour beetle appeared to be located mainly around storages during the winter months, spreading into the surrounding district in summer. This study highlights the importance of finding and dealing with infestations to limit the number of pests that can infest clean grain. In another study, beetles were found to be flying between farms on a scale of at least 100 km.²⁰

NOTE: Exotic pests including Karnal bunt (*Tilletia indica*) and Khapra beetle (*Trogoderma granarium*) are a threat to the Australian grains industry—report sightings immediately.
